

Lab 3 Component modelling and architectural selection

Incident Escalation & On-Call Rotation Engine | Problem 48 | Atharva Anand | PES1UG24CS092

NOTATION Provided interface Required interface Solid: assembly / API call Dashed arrow: usage dependency

- 1 Alert -> coordinator -> rotation lookup -> durable notification request; worker sends through external providers over HTTPS.
- 2 Acknowledgement updates incident state and cancels escalation atomically. Each timer rechecks state before advancing a tier.
- 3 Workers claim durable jobs through IStore; notifications retry with idempotency keys. Console writes pass through the coordinator.

Logical components, not separate microservices. App replicas and worker processes share the business code and repository.
